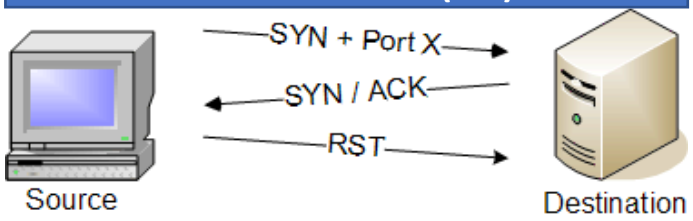
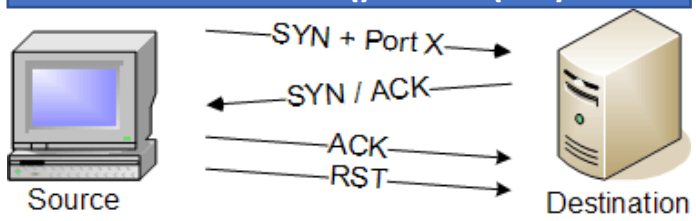
Identifying Open Ports with Nmap

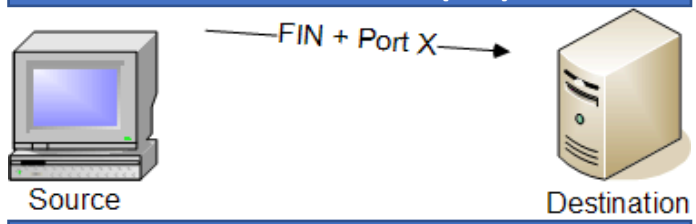
TCP SYN SCAN (-sS)



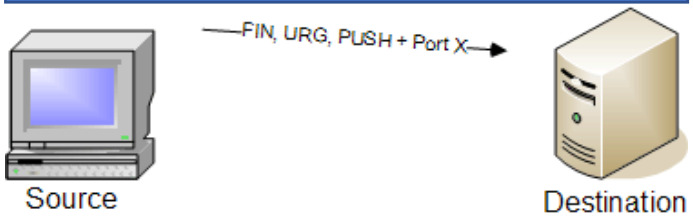
TCP connect() SCAN (-sT)



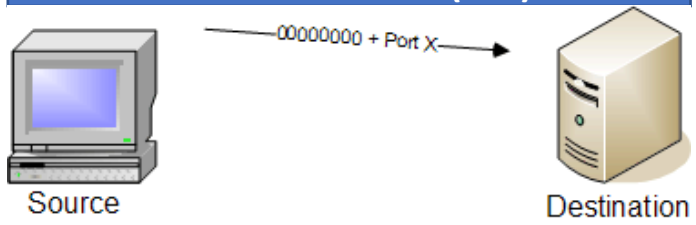
TCP FIN SCAN (-sF)



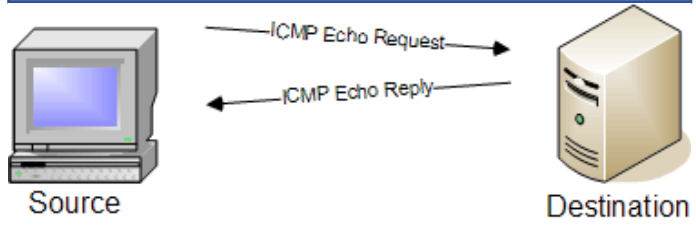
TCP XMAS TREE SCAN (-sX)



TCP NULL SCAN (-sN)

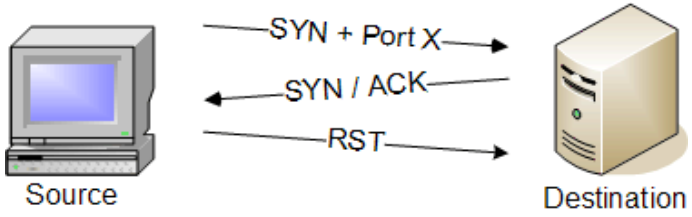


TCP PING SCAN (-sP)

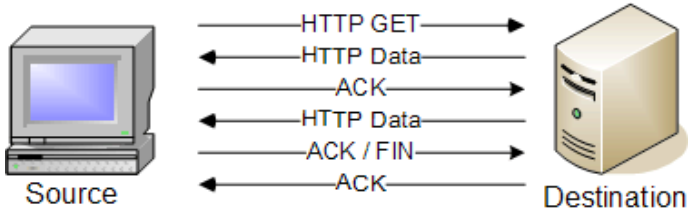


VERSION DETECTION SCAN (-sV)

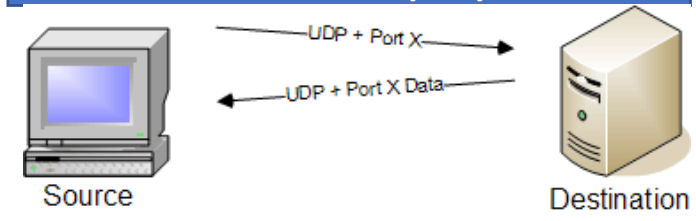
Version scan identifies open pots with a TCP SYN scan…



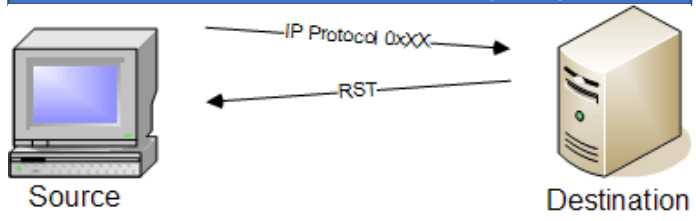
…and then queries the port with a customized signature.



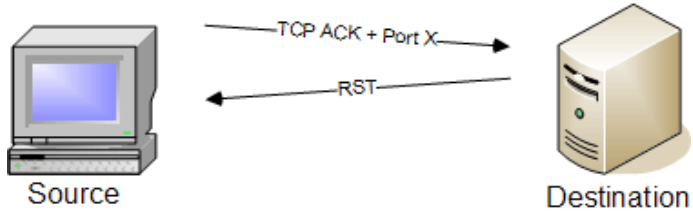
UDP SCAN (-sU)



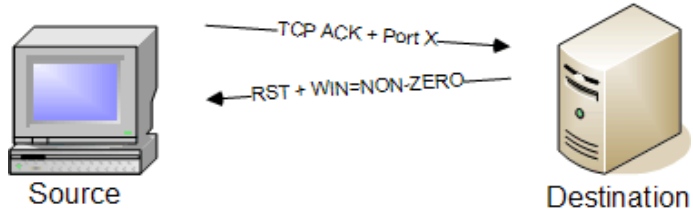
IP PROTOCOL SCAN (-sO)



TCP ACK SCAN (-sA)

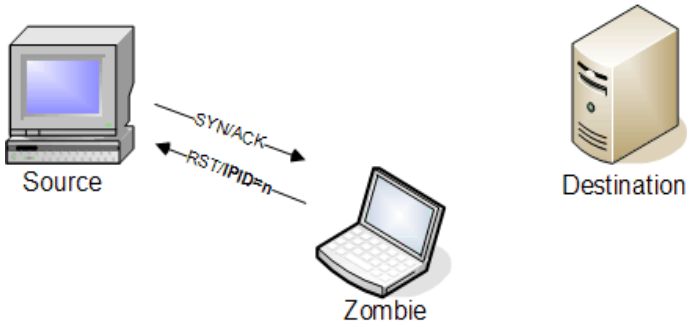


TCP WINDOW SCAN (-sW)

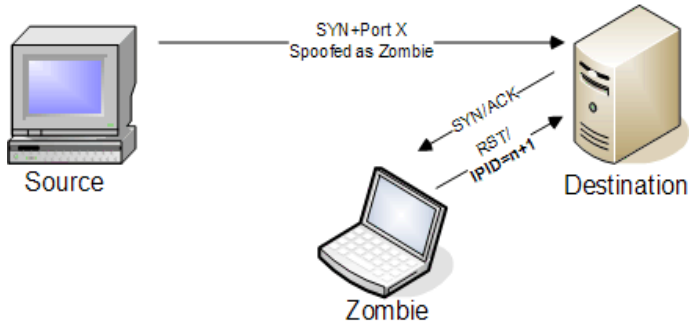


IDLESCAN (-sI <zombie host: [probeport]>)

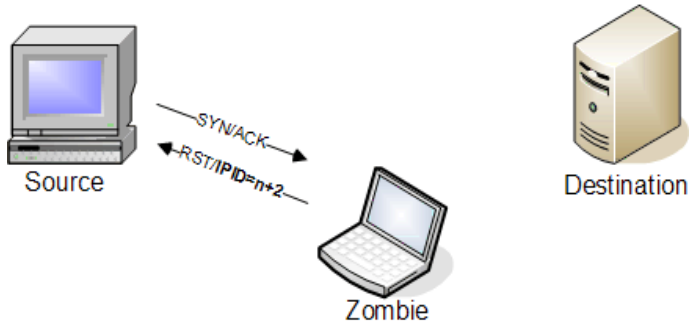
Step 1: Nmap sends a SYN/ACK to the zombie workstation to induce a RST in return. This RST frame contains the initial IPID that nmap will remember for later.



Step 2: Nmap sends a SYN frame to the destination address, but nmap spoofs the IP address to make it seem as if the SYN frame was sent from the zombie workstation.

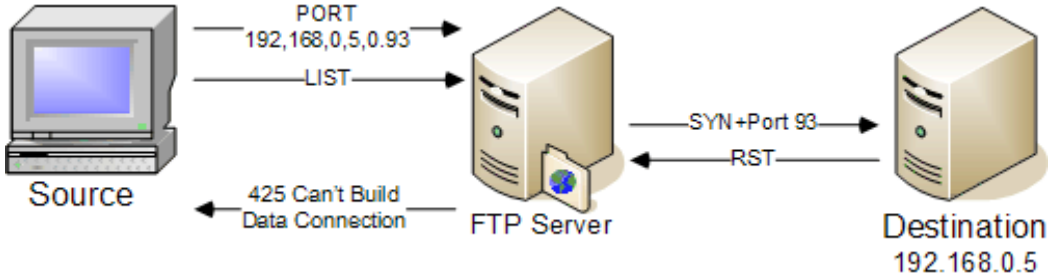


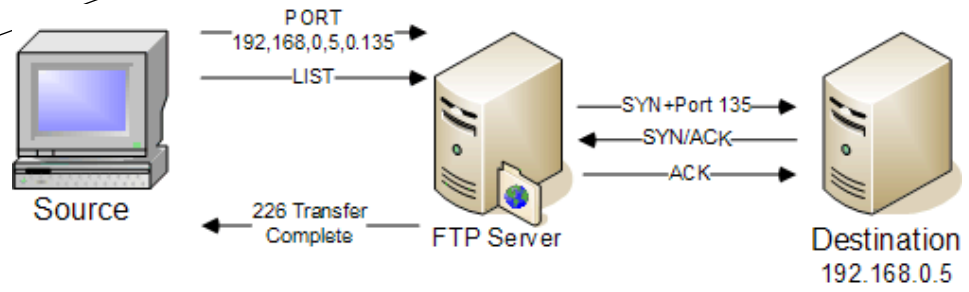
Step 3: Nmap repeats the original SYN/ACK probe of the zombie station. If the IPID has incremented, then the port that was spoofed in the original SYN frame is open on the destination device.



FTP BOUNCE ATTACK (-b <ftp_relay_host>)

A closed port will result with the FTP server informing the source station that the FTP server can't build the connection.





An open port completes the transfer over the specified connection.

NOTE: Be aware that the FTP bounce scan is not workable since most FTP Servers will not perform what is needed for the scan. This is more for information purposes.
